Smallest Covering Window

You are given two strings, s (the text) and t (the pattern).

A substring of s is said to cover t if every character of t appears in that substring at least as many times as it appears in t. Repeated characters in t must be matched by the same number of occurrences in the substring.

Your task is to find the shortest substring of s that covers t.

- If no substring of s covers t, print -1.
- If several shortest substrings cover t, print the one that starts earliest in s.

Characters are case-sensitive: 'a' and 'A' are different.

Input Format

The first line contains the string s. The second line contains the string t.

Constraints

- $1 \leq |s|, |t| \leq 10^5$
- s and t consist only of uppercase and lowercase English letters.

Output Format

Print the shortest substring of s that covers t. If no such substring exists, print -1.

Sample Input 0

```
ADOBECODEBANC
ABC
```

Sample Output 0

```
BANC
```
